Then $\operatorname{Pr}(Z>2 \mid Z>1)$, rounded off to two decimal places, is equal to $\qquad$ _.

Ans. (0.367)
Sol. Cumulative distribution function of 2 is

$$
\begin{aligned}
F_{Z}(x) & = \begin{cases}1-e^{-x} & \text { if } x \geq 0 \\
0 & \text { if } x<0\end{cases} \\
\operatorname{Pdf} f_{Z}(x) & =\frac{d F_{Z}(x)}{d x} \\

25. A standard CMOS inverter is designed with equal rise and fall times $\left(\beta_{n}=\beta_{p}\right)$. If the width of the pMOS transistor in the inverter is increased, what would be the effect on the

LOW noise margin $\left(\mathrm{NM}_{\mathrm{L}}\right)$ and the HIGH noise margin $\mathrm{NM}_{\mathrm{H}}$ ?
(a) $\mathrm{NM}_{\mathrm{L}}$ increases and $\mathrm{NM}_{\mathrm{H}}$ decreases
(b) $\mathrm{NM}_{\mathrm{L}}$ decreases and $\mathrm{NM}_{\mathrm{H}}$ increases
(c) No change in the noise margin
(d) Both $\mathrm{NM}_{\mathrm{L}}$ and $\mathrm{NM}_{\mathrm{H}}$ increase

Ans. (a)
Sol.

For CMOS inverter with equal rise and fall time we have

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{OH}}=\mathrm{V}_{\mathrm{DD}} \\
& \mathrm{~V}_{\mathrm{OL}}=0
\end{aligned}
$$

So, $\quad \mathrm{NM}_{\mathrm{L}}=\mathrm{V}_{\mathrm{IL}}-0=\mathrm{V}_{\mathrm{IL}}$
$\mathrm{NM}_{\mathrm{H}}=\mathrm{V}_{\mathrm{DD}}-\mathrm{V}_{\mathrm{IH}}$
where $V_{I L}=\frac{2 V_{\text {out }}+V_{T, p}+\frac{k_{n}}{k_{p}} V_{T, n}-V_{D D}}{\left(1+\frac{k_{n}}{k_{p}}\right)}$
As width pMOS increased $\mathrm{k}_{\mathrm{p}}$ increases \& $\mathrm{V}_{\mathrm{IL}}$ increases
So, $\mathrm{NM}_{\mathrm{L}}$ increases
$\mathrm{V}_{\mathrm{IH}}=\frac{\mathrm{V}_{\mathrm{DD}}+\mathrm{V}_{\mathrm{T}, \mathrm{p}}+\frac{\mathrm{k}_{\mathrm{n}}}{\mathrm{k}_{\mathrm{p}}}\left(2 \mathrm{~V}_{\text {out }}+\mathrm{V}_{\mathrm{T}, \mathrm{n}}\right)}{1+\frac{\mathrm{k}_{\mathrm{n}}}{\mathrm{k}_{\mathrm{p}}}}$
$\mathrm{V}_{\mathrm{IH}}$ increases and hence $\mathrm{NM}_{\mathrm{H}}$ decreases.

It is transmitted across a channel which adds noise $N$, so that the random variable at the channel output is $Y=X+N$. The noise $N$ is independent of $X$, and is uniformly distributed over the interval $[-2,2]$. The receiver makes a decision

where the threshold $\theta \in[-1,1]$ is chosen so as to minimize the probability of error $\operatorname{Pr}[\hat{X} \neq \mathrm{X}]$. The minimum probability of error, rounded off to 1 decimal place, is $\qquad$ .

(a) 3.89
(b) 2.81
(c) 5.25
(d) 4.50

\mathrm{C}(\mathrm{~s}) & =\frac{1}{\mathrm{~s}(\mathrm{~s}+1)^{2}}

$\mathrm{A}=1, \mathrm{~B}=-1, \mathrm{C}=-1$

$$
\mathrm{C}(\mathrm{~s})=\frac{1}{\mathrm{~s}}-\frac{1}{(\mathrm{~s}+1)}-\frac{1}{(\mathrm{~s}+1)^{2}}
$$

Now applying inverse Laplace transform

$$
\mathrm{C}(\mathrm{t})=1-\mathrm{e}^{-\mathrm{t}}-\mathrm{te}^{-\mathrm{t}}
$$

Steady state value $\lim _{\mathrm{t} \rightarrow \infty} \mathrm{c}(\mathrm{t})=1-\mathrm{e}^{-\infty}-\infty \mathrm{e}^{-\infty}$
