## Class 8: Triangles (Lecture Notes I)

Triangle: We just studied polygons. Triangle is a polygon with three sides. So, we could define a triangle as a plane closed figure bounded by three line segments.

A triangle is a polygon with three edges and three vertices. It is one of the most basic shapes in geometry. A triangle with vertices $\mathrm{A}, \mathrm{B}$, and C is denoted by $\triangle \mathrm{ABC}$.

## Kinds of Triangles

1. This is a classification of triangles based on the length of the sides

| Scalene Triangle | A triangle in which all three sides are <br> of different lengths is called Scalene <br> Triangle. <br> In this type of triangle: <br> $\angle \mathrm{A} \neq \angle \mathrm{B} \neq \angle \mathrm{C}$ |
| :--- | :--- | :--- |
| Isosceles Triangle | A triangle in which two sides are of <br> the same length is called Isosceles <br> Triangle |
| In this type of triangle: |  |
| $\angle \mathrm{B}=\angle \mathrm{C}$ |  |

Some of the diagrams have been adopted from https://en.wikipedia.org/wiki/Triangle

## 2. Classification of Triangles based on the angles

| Acute-angled <br> Triangle | A triangle in which all the three angles <br> are more than $0^{\circ}$ and less than $90^{\circ}$ is <br> called acute-angled triangle. |
| :--- | :--- |
| Right-angles <br> Triangle | A triangle in which one of the angles is <br> $90^{\circ}$ is called right-angled triangle. |
| Obtuse-angled <br> triangle | A triangle in which one of the angles is <br> more than $90^{\circ}$ but less than $180^{\circ}$ is <br> called obtuse-angled triangle. |

Some of the diagrams have been adopted from https://en.wikipedia.org/wiki/Triangle

## Terms related to a Triangle

| Median | A line segment joining the <br> vertex to the mid-point of the <br> opposite side of a triangle is <br> called median. |
| :--- | :--- |
| In this vertex A is meeting at <br> point D (such that $\mathrm{BD}=\mathrm{DC}$ ) <br> midpoint of BC |  |

| Centroid | The point of intersection of <br> three medians is called <br> centroid. |
| :--- | :--- |
| Altitude | The perpendicular drawn from <br> the vertex to the opposite side. <br> Here AD is the altitude of the <br> triangle AD and BC is the base. |
| The intersection of the three <br> altitudes is called the <br> Orthocenter of the triangle. |  |
| Orthocenter |  |
| Angle Bisector | Here A is the Orthocenter of <br> the triangle. <br> Here AD is bisecting $\angle \mathrm{BAC}$ into <br> two equal $\angle \mathrm{BAD}$ and $\angle \mathrm{DAC}$ <br> A line segment that bisects and <br> called angle bisector. |

| Incentre and Incircle | The point of intersection of internal angle bisectors is called the Incentre. <br> I is the Incentre of the triangle. <br> Now if you draw a circle with the center I in such a way that it touches all the three sides of the triangle, then that is called Incircle. | The intersection of the angle 6 bisectors is the center of the incircle. |
| :---: | :---: | :---: |
| Perpendicular <br> Bisector or Right Bisector | A line bisecting any side of the triangle and perpendicular to it is called perpendicular bisector of that side of the triangle. <br> Here $B C$ is being bisected by $D E . B D=D C$ and $E D \perp B C$. |  |
| Circumcenter and Circumcircle | The point of intersection of the perpendicular bisectors of the sides of the triangle is called Circumcenter. <br> Here 0 is the circumcenter. | The circumcenter is the center of a circle passing through the three vertices of the triangle. |
| Exterior Angle and Interior Opposite Angles of a Triangle | $\angle A C D$ is the exterior angle and $\angle C B A$ and $\angle B A C$ are opposite interior angles of this exterior angle. |  |

Some of the diagrams have been adopted from https://en.wikipedia.org/wiki/Triangle
